## Battelle 2023

## 

#### Usage of HRSC Tools to Create More Accurate CSMs at Two Large Manufacturing Facilities

→ May 2023

# Key takeaways

Performed HRSC at two large manufacturing facilities

Completely different CSMs - therefore, different approaches to site characterization

Quickly and accurately characterized sites – significant site characterization cost savings

Accurate CSMs allowed for better FSs and successful implementation of site remedies

## Site 1 Setting

- Located in Michigan
- 1-mile square site
- Historical usage as manufacturing facility and test track
- Test track sold & redeveloped in 1990's
- No drinking water wells on or adjacent

## Background

- Prior to the RI, an extensive Phase II ESA was completed using traditional investigative methods. Findings from the Phase II ESA indicated the presence of TCE at the property boundary
- •TCE identified in intermediate interval of ~30ft-thick sandy aquifer

## **Remedial Investigation**

#### **RI included**:

- Membrane Interface Probe (MIP)
- Hydraulic Profiling Tool (HPT)
- Traditional drilling and sampling
- Aquifer testing
- •3-D models
- •TCE Isotope analysis
- Treatability studies

#### **Remedial Investigation**

The extensive size of the site and the thin plumes of TCE present, MIP technologies were utilized to rapidly identify and delineate the vertical and horizontal extent of TCE

> Gas Chromatograph (GC) Field Instrument

É

MIP Probe

#### **Remedial** Investigation

#### **MIP/HPT Remedial Investigation**

- Over 300 MIP/HPT locations were completed, typically in north-south transects oriented perpendicular to groundwater flow direction
- MIP data used to direct traditional RI data collection

#### **Conceptual** Site Model

#### **TCE Characterization**

- TCE plumes extend ~½ mile downgradient
- Present in 1-to 3-ft-thick interval within the intermediate portion of the sandy aquifer ~10 ft below water table
- Analytical data confirmed primary COC was TCE
- TCE detected at a maximum concentration of 4,500 µg/L

#### **Conceptual** Site Model

Based on CSM – FS completed selecting PRBs at downgradient edge of plumes

#### **Pre-Design** Investigation

- 3D fate & transport model
- Temporary and permanent monitoring wells to verify exact location of plume for PRB locating
- Soil borings along path of proposed PRB to better define stratigraphy
- Slug tests and collection of soil for grain size and permeability tests
- HPT data was consistent w traditional testing method results

#### **PRB** Design

PRB identified in red, tying into the lower clay unit

## Site 2 Setting

- -Located in Indiana
- -148-acre site
- Recently demolished main building ~1.6M square feet
- Primarily a flat site
- No drinking water wells onsite or adjacent sites

#### Background

#### Site Investigations

- 400+ soil borings
- 260+ Temporary & permanent monitoring wells installed
- Surface Geophysics

Using high-resolution site characterization tools – GRID PATTERN

– LIF

– MIP

- 280 MIP borings
- Identified cVOCs

- 158 LIF borings
- Identified LNAPL

#### **MIP Results and Interpolation**

#### **LIF Results and Interpolation**

Battelle 2023 | GHD

#### Geology

- Surficial Fill
- Native Clay (75 ft)
- Discontinuous Interbedded -Sand Units (various depths within the native clay unit)

#### Groundwater

- Depth to water typ. 8 10 ft below grade
- Native Saturated Sand
  Units Semi-Confined to
  Confined

#### **Constituents of Concern (COCs)**

- Under Main Plant Floor TCE, 1,1,1-TCA, Other VOCs, SVOCs & Oil (LNAPL & DNAPL)
- Chip Shed TCE & Other VOCs & Oil (LNAPL)
- Western Property Boundary TCE & Other VOCs
- Sources of Impact
- Oil multiple oil containment systems (USTs, pits, vaults, trenches, sumps)
- TCE/VOCs used equipment storage area (western property boundary), parts vapor degreasers, solvent dip tanks, former waste transport lines

#### **Conceptual Site Model**

- LNAPL at water table
- TCE, TCA & other VOCs primarily from 5 25 ft bgs
- DNAPL at 15-25 ft bgs

## Final remedy approach

- Risk Assessment no active remediation was required as long as an ERC was placed on the property
- Client selected source area remediation

 WP prepared to select and document how the source areas would be treated in combination with an ERC

## **Feasibility Evaluation**

Residual Hydraulic Oil – shallow soil & GW (0 - 12 ft) Institution Controls – Restrictive Covenant Solvents – shallow zone soil & GW (0 – 25 ft) In-Situ Thermal Remediation

## Summary

×	<b>Site 1</b> - MIPs completed in transects perpendicular to GW flow	Identified three separate TCE plumes; 2 were long thin dilute plumes	N K	TCE present in 0.5 to 5.0 ft thick interval in middle of aquifer	×	HRSC tools created more accurate CSM & successful remedy
×	Site 2 – MIPs & LIFs completed in grid pattern	Identified 12 source areas including LNAPL, DNAPL & cVOC impacted soil & GW		VOCs & NAPL present at depths varying from surface to 25 ft bgs	Ŧ	HRSC tools created more accurate CSM & successful remedy
